## DEFINITION 1

- The *doubling time* of an exponentially increasing quantity is the time required for the quantity to double.
- The *half-life* of an exponentially decaying quantity is the time required for the quantity to be reduced by a factor of one half.

COMPOUNDING  
INTEREST

The release of chlorofluorocarbons (CFCs) used in air conditioners and household aerosols destroys the ozone layer in the upper atmosphere. The quantity of ozone,  $Q(t)$ , decays exponentially at a continuous rate of 0.025% per year. What is the half-life of ozone?

The half life is given by

$$\begin{aligned}\log_{e^k}(2) &= -\frac{\ln(2)}{\ln(e^k)} \\ &= -\frac{\ln(2)}{k} \\ &= -\frac{\ln(2)}{-\frac{1}{400}} \\ &= 400 \ln(2) \approx 277 \text{ years.}\end{aligned}$$
